ESA UNCLASSIFIED – For ESA Official Use Only

Event-based cameras as hardware retinal models

Basic idea: convert analogue visual into events

- Capture (logarithmic) **changes** in illumination
- If the change is greater than a threshold, produce an event (spike)
 - The change can be in either direction
 - Reset the threshold to the current input
- Completely **asynchronous** pixels!

Credit: Metavision®

Shortcomings of classical vision-based sensors

- Limited dynamic range (edge detection)
- Limiting configurations / illumination conditions (Sun-facing, reflectors)
- **Unnecessary data acquisition and processing**
 - High data rates required for fast acquisition
 - Compromise resolution / acquisition rate

Event-based cameras

- High dynamic range
 - Sparse event output
 - Low power consumption
 - Low latency
 - High temporal resolution
- Applications for Pose Estimation, Planetary Landing, RV&D

- Collaboration with TEC-SAG : DAVIS 346 camera
- Use of the GRALS facilities (mechanical arms)
- Reconstructing optical flow using spiking neural networks

More realistic retinal models

- A hierarchy of artificial sensors that mimic retinal cells
- But only in simulation for now
 - We want to implement it in hardware to make it work in real time!

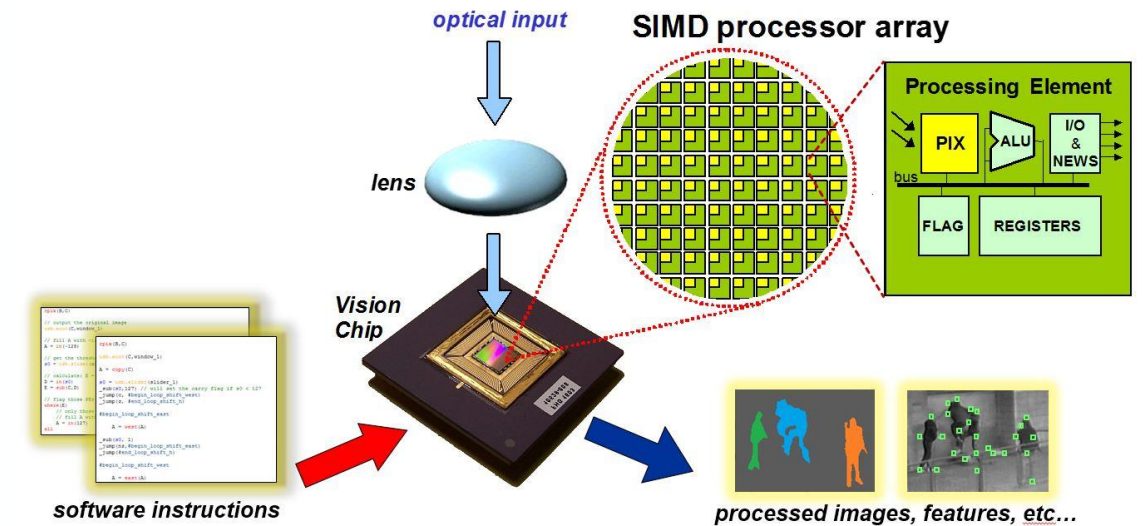

Simulation of adaptive retinal model

More realistic retinal models

- A hierarchy of artificial sensors that mimic retinal cells
- But only in simulation for now
 - We want to implement it in hardware to make it work in real time!

Candidate hardware platforms

- SCAMP5 analogue sensor
 - Massively parallel architecture
 - Very low power consumption
 - Easy to implement various CV algorithms
 - Most of the advantages of current event-based cameras with less artifacts and drawbacks
