

Cosmic Rays backtracing in the Earth Magnetic Field: the importance for AMS-02 of the External Models during the last solar period data taking (from 2011 to 2013)

**Davide Grandi
INFN – Milano Bicocca**

Summary

- The Earth Magnetic field Field
 - Internal & External Field (TS96 & TS05) GOES & Cluster Magnetic Field data
 - Our Magnetic Field model
- CR trajectory reconstruction
 - Particle nature Primary vs Secondary
- Back Tracing with/without TS05
 - Internal vs External Magnetic Field
 - Simulation
 - AMS-02 data & solar flares
- Conclusions

The Earth Magnetic Field

The Earth magnetic field can roughly be considered as a dipole, whose axis is tilted with respect to the rotation axis and whose center is shifted with respect to the Earth's center.

$$B_e = 0,5 \text{ Gauss}$$

$$B_{IMF} = \text{few nT}$$

Due to the compression of the solar wind it becomes widely asymmetric with a long tail opposite to the Sun

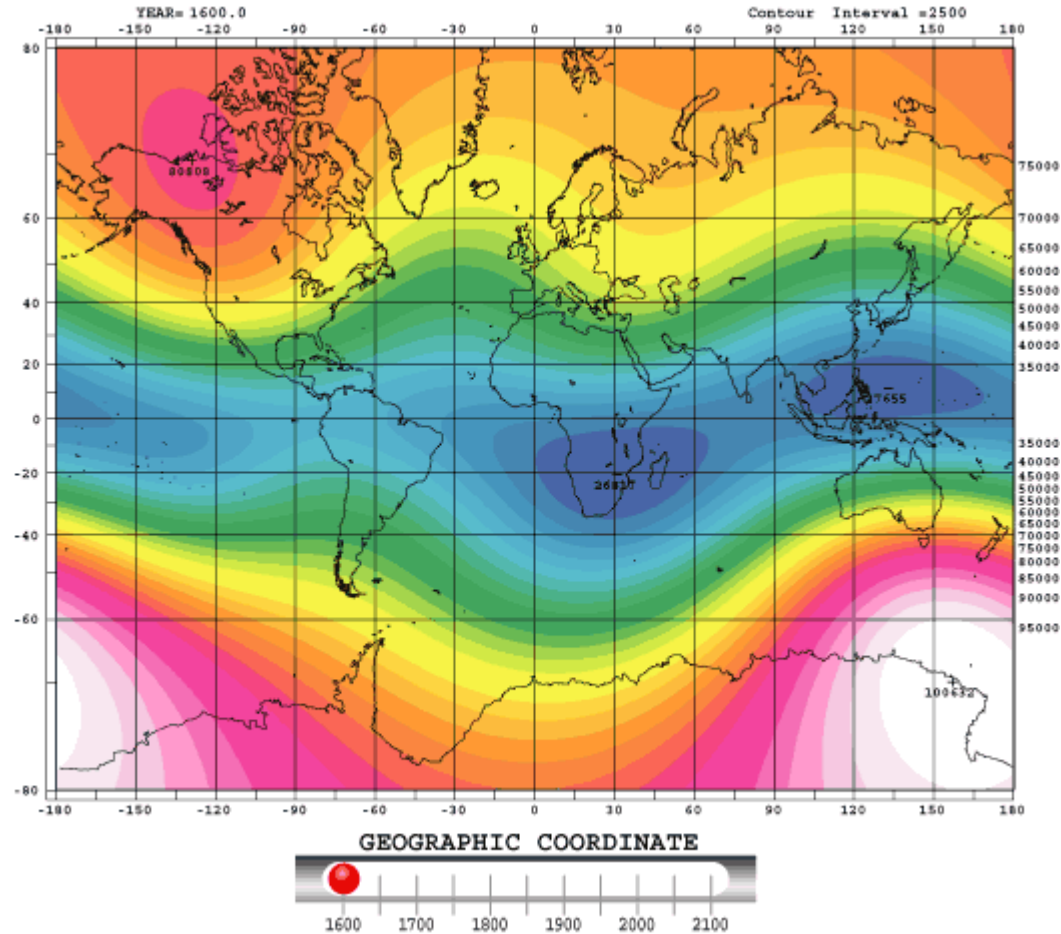

Internal Field

IGRF 11 latest model is a standard mathematic description of the Earth main magnetic field and its annual rate of change (secular variation).

In source free regions this main field is the negative gradient of a scalar potential V , represented by a truncated series of spherical (13th order) harmonic expansion

$$\mathbf{B} = -\nabla V$$

$$V = R_e / \Sigma \Sigma (R_e / r)^{n+1} [g_n^m(t) \cos m\phi + h_n^m(t) \sin m\phi] P_n^m(\cos \vartheta)$$

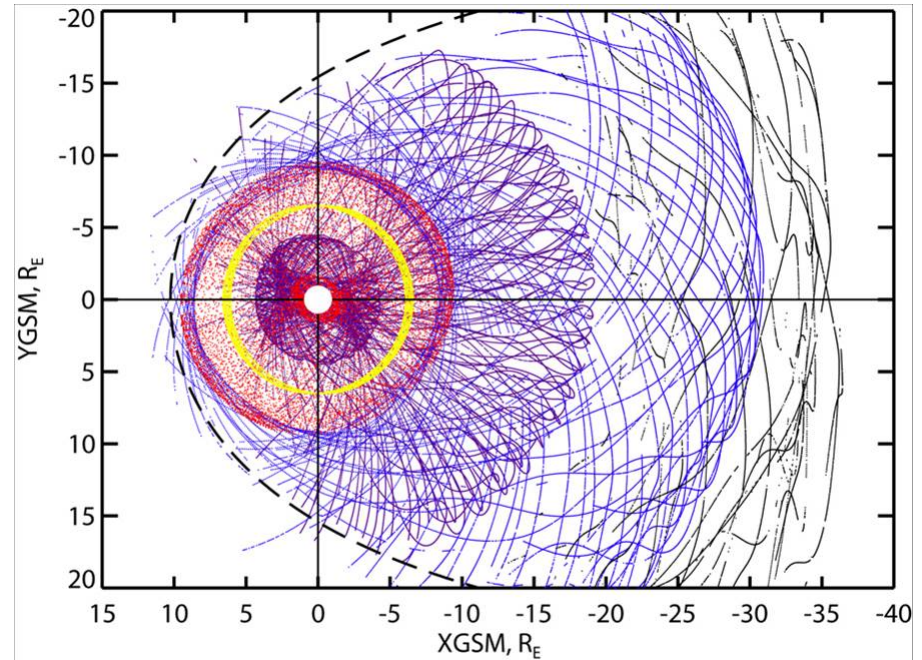

<http://www.ngdc.noaa.gov/AGA/vmod/igrf.ht>

External Field

Tsyganenko models:

- Data base approach from over 3 decades of measurements...
- All external currents contributions to external magnetic field
- 1996 model (solar wind controlled magnetopause Sibeck)
- 2001 and 2005 models (for SEP and CME events)

<http://geo.phys.spbu.ru/~tsyganenko/modeling.html>

Tsyganenko 96

Depends on 4 main parameters: Dst, Pdyn By and Bz of IMF)

Contains these main Magnetic field contribution:

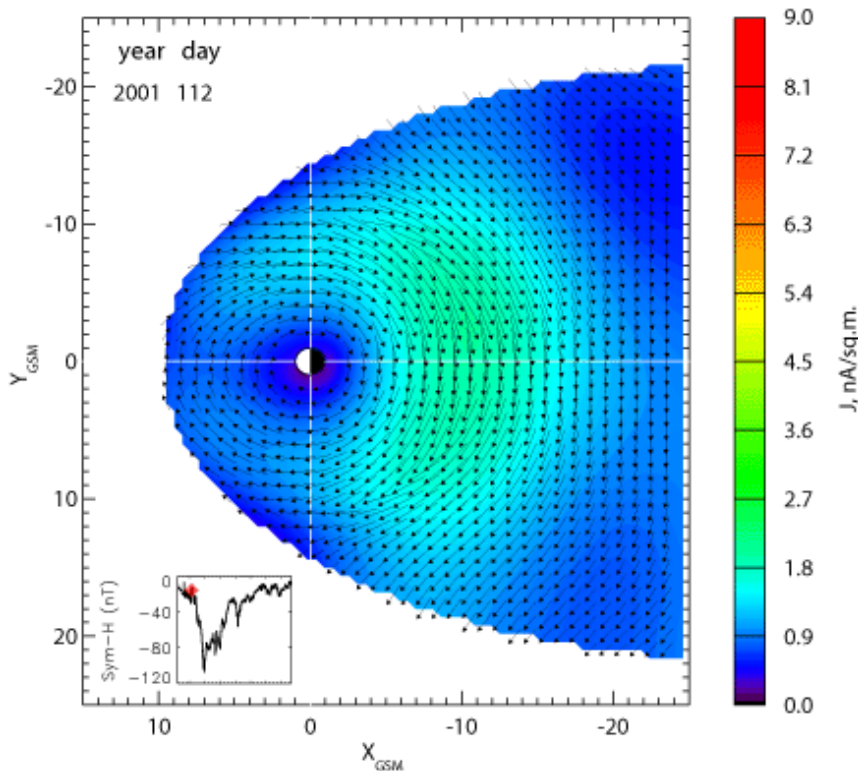

- Magnetopause
- Ring Current (trapped)
- Tail current
- Bierkeland region 1
- Bierkeland region 2
- Interconnection field

All fields are empirically obtained by the 4 main parameters

<http://geo.phys.spbu.ru/~tsyganenko/modeling.html>

Tsyganenko 05

New data from 1996 to 2000
(37 major events)

All components from 3 main
parameters:

1. N density of SW
2. V speed of SW
3. B southward IMF components

Time scale of Tsyganenko 2001 is 1 hour, (symmetric rise and decay of solar event) while with Tsyganenko 2005 becomes asymmetric.

Plus in addition there is a Fast and Slower response of each Magnetic field component to the Storm

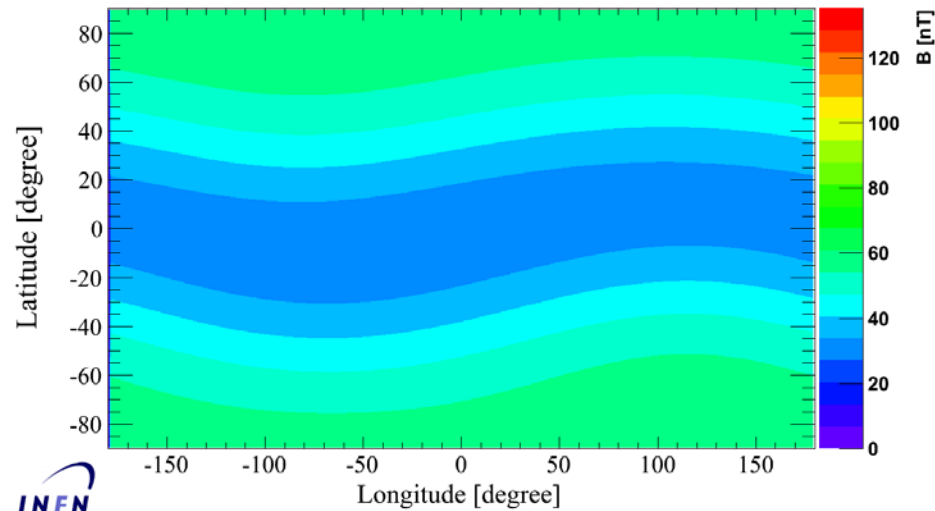

<http://geo.phys.spbu.ru/~tsyganenko/modeling.html>

External Field for GOES data

Figure 1. D_{st} and geostationary magnetic field during a major storm on 25 September 1998 in universal time. Panel (b) shows the GOES-8 GSM B_z magnetic field (in black) and the Tsyganenko model predictions at GOES-8's position (T96 in green, T02 in blue, and TS05 in red). The predicted B_z value include the IGRF and the model external field.

- GOES measurements compared with External field models (T96, T02 and TS05) during solar storms
- Added IGRF and compared B_z (long Dst minimum - 213 nT)
- TS05 is better (residuals are smaller) and not anomalously strong negative B_z

Figure 4. The residual fields (ΔB_z) between GOES data and Tsyganenko model outputs in different local time and D_{st} bins (T96, T02, and TS05, from left to right, respectively). The median data value is picked to represent all data points in each bin. The color scales of each panel are identical, from -35 to $+40$ nT. A white pixel marks a bin with no data.

External Field for Cluster data

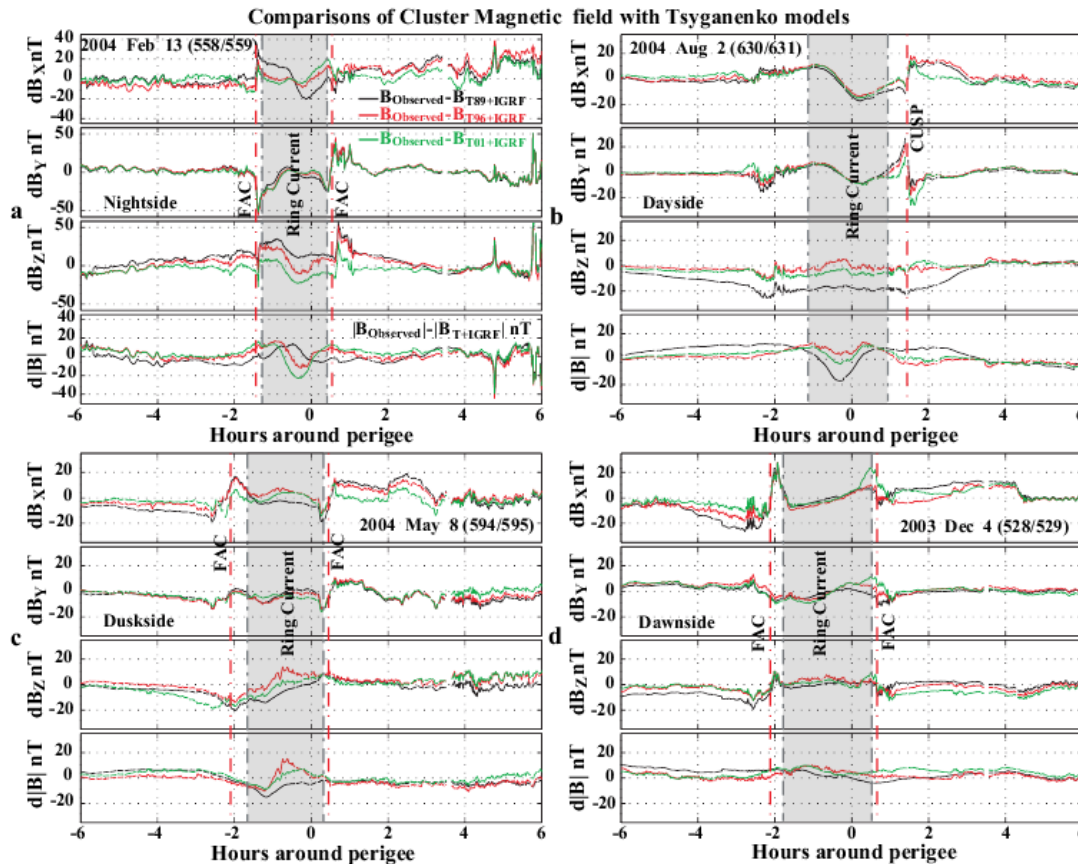

Fig. 4. Residuals from the comparisons of Cluster S/C 1 observations with T89 (black), T96 (red) and T01 (green) and IGRF (magenta) models for the nightside pass on 13 February 2004 (a), dayside pass on 2 August 2004 (b), duskside pass on 8 May 2004 (c) and dawnside pass on 4 December 2003 (d). From top to bottom panels of Fig. 5a–d are for the dB_{XGSM} , dB_{YGSM} , dB_{ZGSM} and the magnitude of the field. The black vertical lines show the ring current region crossing.

- Cluster measurements compared with T89, T96 and T01
- subtracted static IGRF to obtain only the external component.
- all models have some “problem” for the Ring Current (grey zone in the figure)
- T01 (precursor of TS05) performs better (the residuals are much smaller)

CR trajectory reconstruction

Particle trajectory is reconstructed back in time with “actual” magnetic field model to distinguish between allowed and forbidden trajectories (i.e. primaries and secondaries CR)

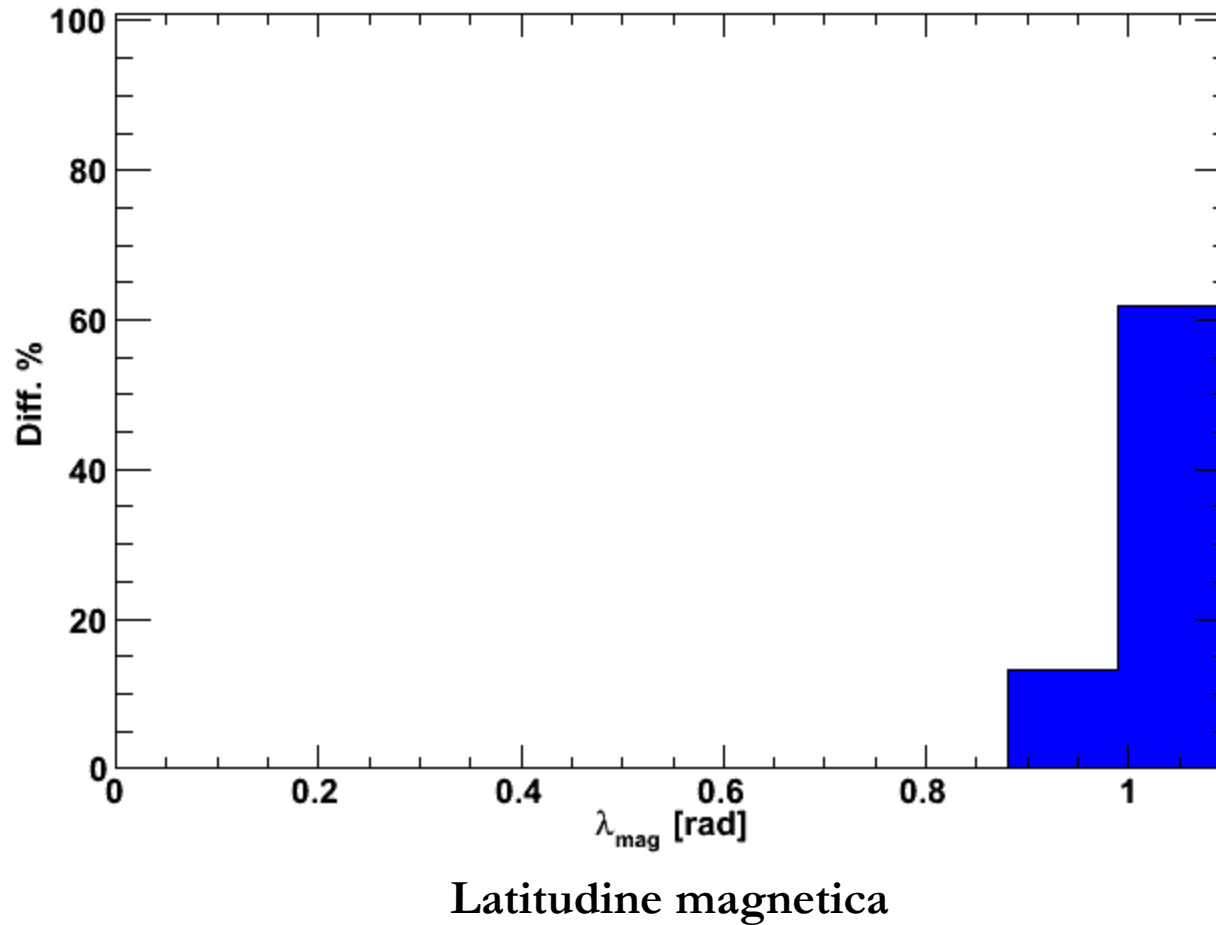

CR trajectory reconstruction

Parameters of the test:

1. 20 energy bins from 300 MV to 200 GV
 2. From -50 to +50 in lat and 360 in long (756 pos)
 3. 13 bins in incoming lat and 13 in incoming long (inside a cone of 60° from zenith this considering a situation AMS-02 like)
 4. Total particles simulated 2.5×10^6
- Almost 18% of the particles were recognized as **secondaries** CR (forbidden trajectories) only with IGRF-11 while they were **primaries** if External field was applied, 2% of the cases is the viceversa.
 - The difference was dominant in the “**polar**” regions where it could
 - Reach **100%** of the sample., for rigidities below 10 GV
 - The test was done in quiet solar periods .

CR trajectory reconstruction

R < 0.3 GV

Internal vs External– Final point difference

- Test we performed with primary CR (May 2011~ dec 2012)
- Precision of the reconstructed trajectory at the border of the magnetosphere.
- Used the last magnetopause model of Shue (whose boundary size depends on SW pressure and IMF)
- Sample for this analysis is 2.2×10^5 AMS **electrons**.
- Evaluated the difference between last point direction (magnetosphere) for different rigidity bins separated for Latitude and Longitude
- This decrease increasing the rigidity and is bigger with and without the external field

IGRF –TS05 : Latitude difference

$20 < R < 30$ GV

$R > 50$ GV

IGRF –TS05 : Longitude difference

$20 < R < 30$ GV

Asimmetry: due to dipolar field and negatively charged particles (electrons) curvature is mainly westward..

$R > 50$ GV

Internal vs External

TS05 or IGRF?

	RMS in mrad		
	All	P<4nPa	P>4nPa
Latitude NoExt-T05	10.9	10.3	18.2
Longitude NoExt-T05	13.6	12.9	21.6
Latitude T96-T05	3.5	3.3	6.7
Longitude T96-T05	5.0	4.5	8.8

**T05 for disturbed periods
and T96 for “quiet” ones**

Conclusions

- With our study (and previous ones) we could verify that magnetic field measurements are in good agreement with predicted values with T05 (while simple IGRF is not precise enough especially in outer magnetosphere)
- T05, developed for storm periods, is even better in high solar activity periods like that one in which AMS-02 is taking data.
- The nature of Primary Cosmic rays highly depend on the magnetic field model, even up to 80-100% at high geomagnetic latitudes
- Even at high energy, so only for primary Cosmic Rays, the magnetosphere structure and an accurate Magnetic Model is important
- Our code, part of the AMS02 official one, has been used for the ongoing AMS-02 analysis for Solar Flares protons showing a big difference in separation of Primary and Secondary CR using or not the External Field (TS05)
