

15th Geant4 Space Users' Workshop  
December 2023 - Pasadena, CA

# Advancing Radiation Hazard Simulations in Spacecraft Environments With SPENVIS GEANT4 Tools

M. Laura Sorgi Johann  
Research Advisor: Dr. Bereket Berhane  
Embry–Riddle Aeronautical University  
Daytona Beach, FL

# Introduction

## **Polymer Matrix Composites Interest:**

- Several combinations of polymer-based matrix + infills composites have been proposed.
- Composites allows orbit specific mass optimization by selecting the type and percentage of infills based on the radiation hazard.

## **Undermining Additional Structures:**

- Such studies often overlook additional structures like external hulls, racks, and MMODs.
- These structures significantly alter the radiation nature that the shields are designed to counter.

## **Challenges in Modeling Complex Materials:**

- Modeling complex, inhomogeneous materials, including polymer based composites and these additional structures, requires extremely simplified assumptions.

# Material Stopping Power

- The rate of electronic energy loss of a heavy charged particle is proportional to the electron number density of the target material ( $\sim \rho Z/A$ ).
- Above critical energy, radiative energy loss for electrons dominate, so the efficiency of material stopping power scales with  $Z^2$ .
- Critical energy is inversely proportional  $Z$ .

$$-\left\langle \frac{dE}{dx} \right\rangle_e \propto \rho \frac{Z}{A}$$

e for electronic

$$-\left\langle \frac{dE}{dx} \right\rangle_r \propto \rho \frac{Z^2}{A}$$

r for radiative

# Combined Effects in Mixtures

- The combined efficiency of materials is determined by the linear combination of their stopping powers (Bragg additivity) [Martin J. Berger, 1988].
  - Ion stopping power benefits on hydrogen content (high  $Z/A$ ) and bond strength in material such as polymers.
  - Electron stopping power can be optimized by choosing infills prone to radiative loss processes (high  $Z$ ).
  - Gamma mass attenuation can be optimized with high  $Z$  infills to be more photoelectric prone ( $\sim Z^5$ ).

$$\left\langle \frac{dE}{dx} \right\rangle = \sum w_j \left\langle \frac{dE}{dx} \right\rangle_j$$

$$\sum w_j \frac{Z_j}{A_j} = \frac{\sum n_j Z_j}{\sum n_j A_j}$$

$w_j$  is the fraction by weight of the  $j$ 'th constituent

# SPENVIS Definitions & Steps to Model Complex Structures

# Space Environment in SPENVIS

- Environment definition is provided by SPENVIS in terms of Geant4 General Particle Source (GPS) format:
  - Trapped proton and electron fluence
  - Solar particle mission fluences
  - Galactic cosmic ray (GCR) fluence
- Based on defined mission orbit.

# Multi-Layered Shielding Simulation (MULASSIS)

- The integrated GEANT4 tool MULASSIS is used for modeling 1D materials.
- User defined material definition requires chemical composition and density.
- The geometry of materials are limited to homogeneous layers.

**Adding new material**

# Challenges of Inhomogeneous Materials

- Combining chemical formulas requires dubious assumptions about the material density and dispersion.
- Density variations can render the density correction factor in the Bethe's equation inaccurate, especially for stopping powers dominated by electronic loss, challenging the reliability of Bragg's rule [Martin J. Berger, 1988].

	COLLISION STOPPING POWER (MeV-cm <sup>2</sup> /g)		Percent Difference
	0.1	3.674	
1	1.617	1.609	-0.5
10	1.745	1.730	-0.9
100	1.950	1.928	-1.1
	Density 1.7 g/cm <sup>3</sup>	Density 2.265 g/cm <sup>3</sup>

# ISS Dose Survey

- 2020 ISS Columbus module dose assessment [L. Di Fino, 2023]:
  - Average directional daily up to 180 microGy(Si) (540 microGy(Si) for omnidirectional).
  - Peak dose rate of 30 nGy(Si)/s during the South Atlantic Anomaly (SAA) segment.

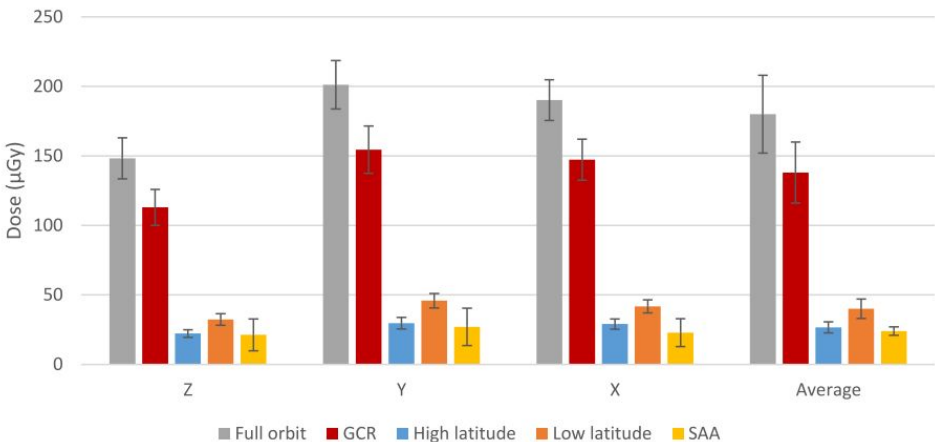

Di Fino, L., et al., Radiation measurements in the International Space Station, Columbus module, in 2020–2022 with the LIDAL detector, Life Sciences in Space Research, 2023.

# Benchmarking Simulated ISS

Surveyed

Integrated Dose per Day

0.018 rad(Si)/day = 6.57 rad(Si)/year

Modeled

Modeled ISS TID by Radiation Sources

7.12 rad(Si)/year

# Shielding Efficiency & Dose

- Total energy deposited overlooks critical factors that define the efficiency of shields for multiple purposes.
- Addressing fluence of secondary radiation broadens shield study applicability:
  - Can still shed light on relative biological effectiveness.
  - Benefit the growing interest of in-space production (pharmaceutical, semiconductor, optical manufacturing).

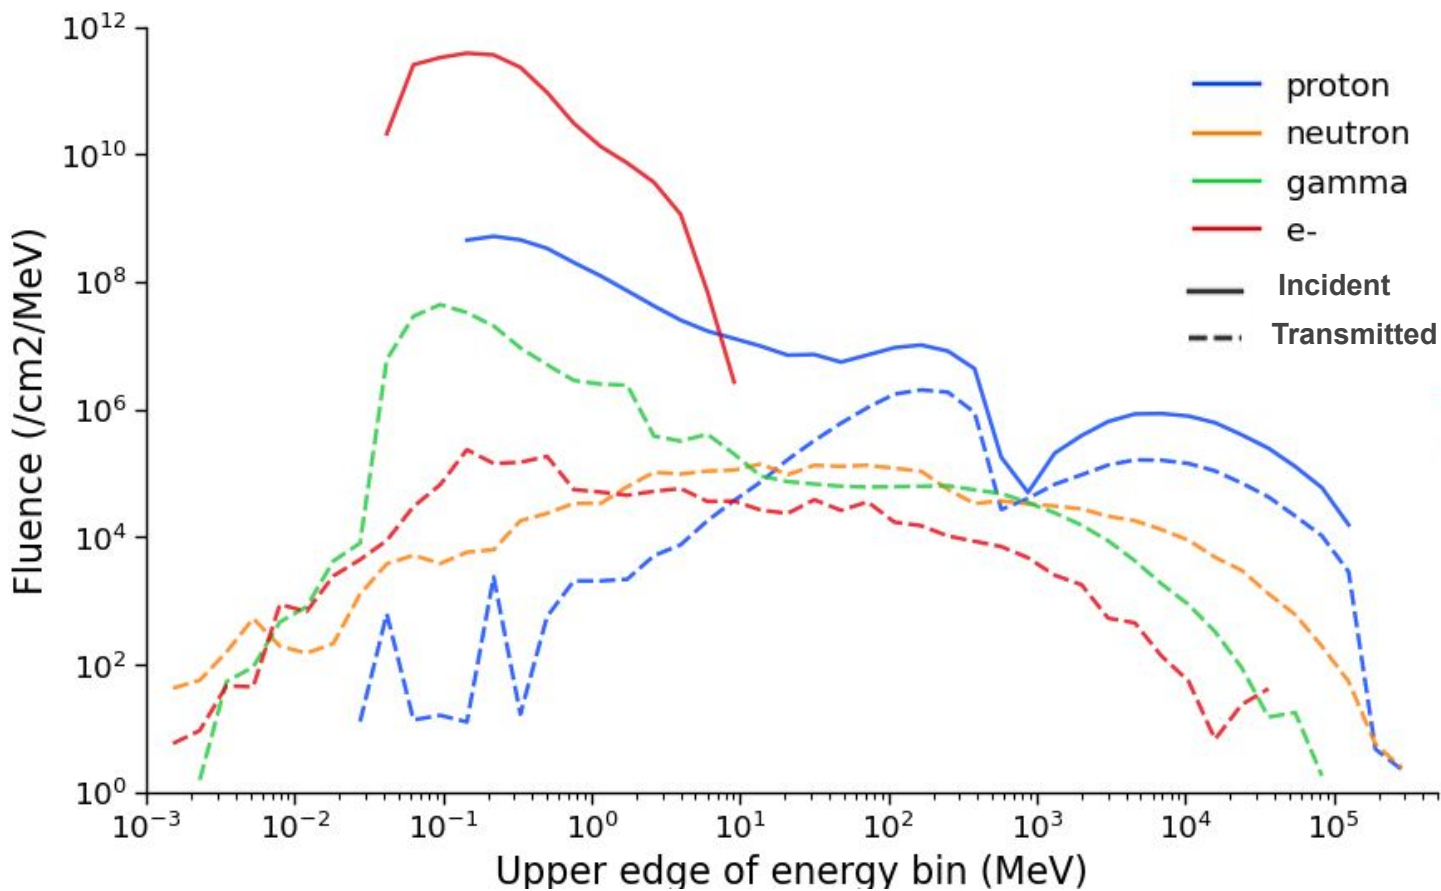

Space Production Applications  
(InSPA) NASA.gov

# Fluence Assessment for ISS Shields

- Thus, for an all encompassing study, we urge for the use of fluence  $\phi(E)$  (/cm<sup>2</sup>/MeV).
- In this work:
  - Comparing incident vs transmitted fluence ( $\delta\phi(E)$ ) for popular proposed materials to emphasize efficiency declination when existing structures considerations are overlooked.
  - Fluence absorbed fraction (Incident vs transmitted for radiation type over total incident fluence):  $(\delta\phi/\phi_i)_{\text{radiation}} = (\phi_t - \phi_i)_{\text{radiation}} / \sum \phi_i$

### Fluence Spectra Before and After ISS Shield by Radiation Type

# Materials Explored

<b>MLI</b>	Al 6061-T6 2 mm	
		3.12 mm
	6 Nextel AF62 8.4 mm (6x1.4 mm)	
6 Kevlar KM2 Fabric 2.1 mm		
Al 2219 -T87 4.8 mm		
<b>Added Shield Layer</b>		

Wt% = particle infil weight percent

Separated by “|” = Layered

Added Areal Density (g/cm <sup>2</sup> )	Material	Infill Wt% or Layer Ratio	Added Thickness (mm)	
-	ISS	N/A	-	
2.84	Al	N/A	10.0	
	Pb	N/A	2.5	
	PE		N/A	30.2
			30% WO <sub>3</sub>	10.1
			30% Gd <sub>2</sub> O <sub>3</sub>	9.9
			15% WO <sub>3</sub>	15.2
		15% Gd <sub>2</sub> O <sub>3</sub>	14.9	
	PF		N/A	25.8
			15% WO <sub>3</sub>	14.1
			15% Gd <sub>2</sub> O <sub>3</sub>	13.9
10.00	Al	N/A	35.2	
	Pb	N/A	8.8	
	PE		N/A	106.4
			15% WO <sub>3</sub>	53.4
		15% Gd <sub>2</sub> O <sub>3</sub>	52.4	
	PF	N/A	90.9	
	Pb PE		1:1	57.6
			1:3	77.1
PE Pb		1:1	57.6	

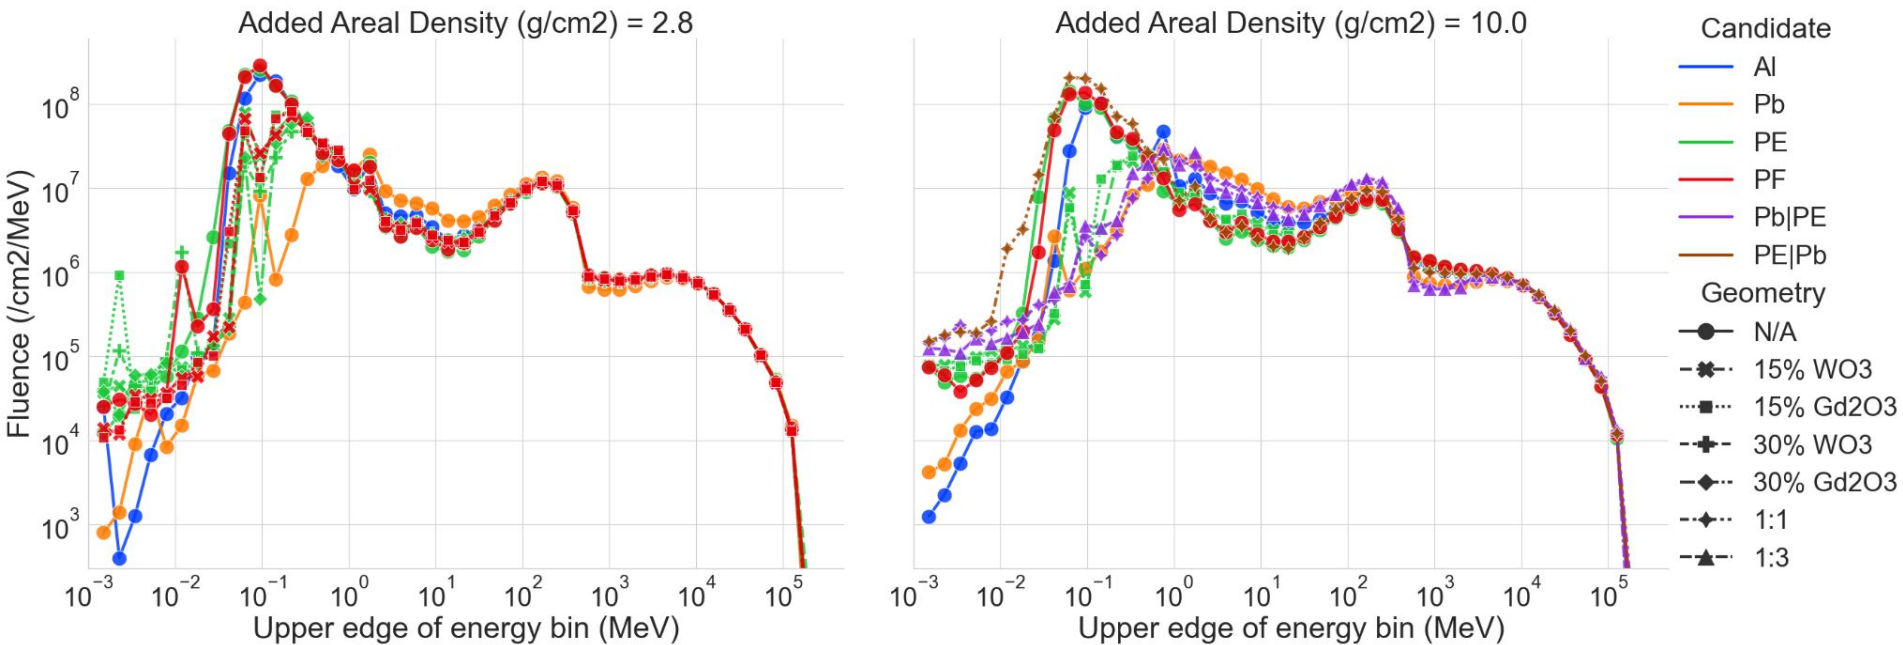

- No additional shielding for low-energy (<100 MeV) protons beyond the ISS baseline demonstrated enhancements.
- Equal improvement in low-energy electron shielding observed across all candidates.
- Low-energy secondary product fraction minimal across.

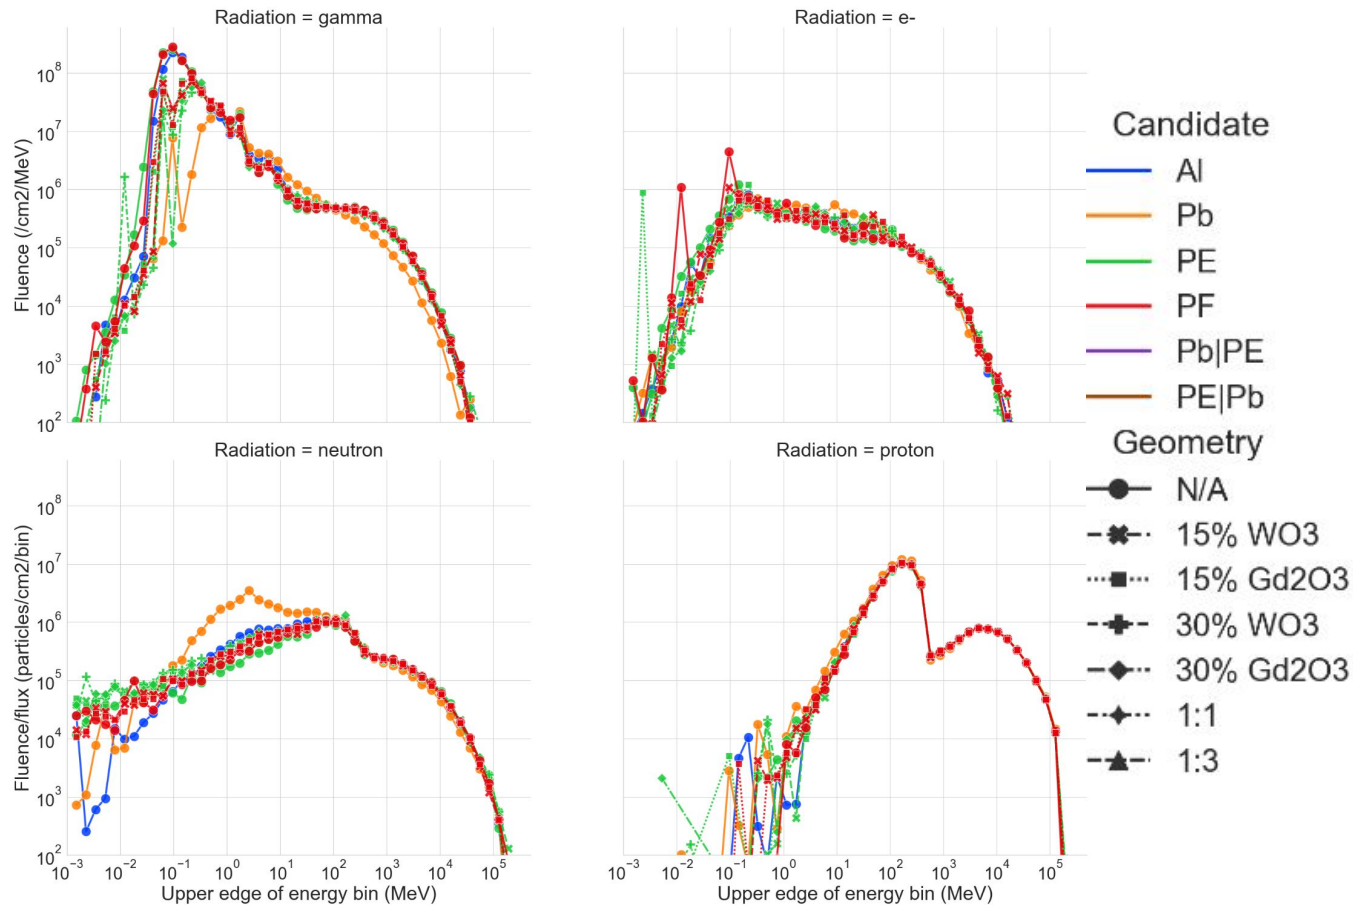

- Improvements for high-energy (>100 MeV) proton shielding could include as little as 2.8 g/cm<sup>2</sup> of added areal density.
- Increased areal density and/or atomic number (Z) in materials lead to higher production of secondary neutrons and gamma particles.

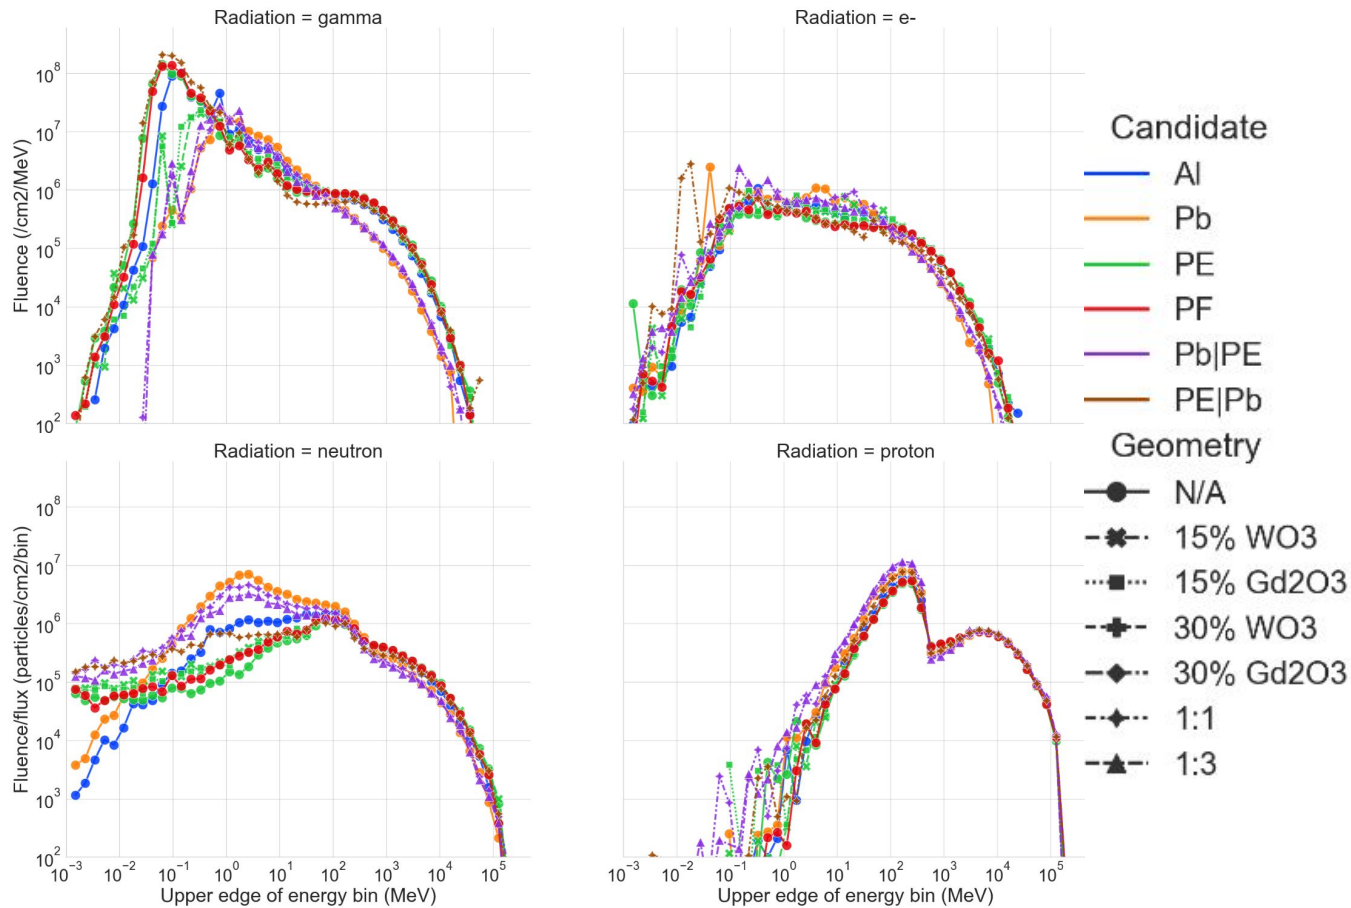

### Fluence Spectra Through ISS + Shield Candidates

Fluence Spectra Through ISS + 2.8 Areal Density (g/cm<sup>2</sup>) Added by Shield Candidates

Fluence Spectra Through ISS + 10.0 Areal Density (g/cm<sup>2</sup>) Added  
by Shield Candidates

# Thank you!
