Conclusion

Effect of DSSS

Security Properties: Unobservability

- Increasing the chip rate increases the bandwidth
- Select *chips per bit* to detect signal beneath noise floor
- **Unobservability** – adversaries without knowledge of $\tilde{P}N$ cannot detect presence of signal

Effect of DSSS

Security Properties

- **Secrecy** – data is encrypted at PHY-layer
 - **Unobservability** – adversaries without knowledge of $\tilde{P}N$ cannot detect presence of signal
- **Availability** – chips per bit can be scaled to provide required jammer tolerance
- **Authenticity** – as much as provided by XOR with random sequence

Effect of DSSS

Security Properties

- **Secrecy** – data is encrypted at PHY-layer
 - **Unobservability** – adversaries without knowledge of $\tilde{P}N$ cannot detect presence of signal
- **Availability** – chips per bit can be scaled to provide required jammer tolerance
- **Authenticity** – as much as provided by XOR with random sequence

Each depends on *secrecy of spreading sequence $\tilde{P}N$*

Effect of DSSS

Security Properties

- **Secrecy** – data is encrypted at PHY-layer
 - **Unobservability** – adversaries without knowledge of $\tilde{P}N$ cannot detect presence of signal
- **Availability** – chips per bit can be scaled to provide required jammer tolerance
- **Authenticity** – as much as provided by XOR with random sequence

Each depends on *secrecy of spreading sequence $\tilde{P}N$*

Therefore $\tilde{P}N$ should be a **cryptographic random sequence**

Hybrid Cryptographic/CDMA Spread Spectrum

Mechanism Overview

- Spreading sequence cryptographically random since XORed with $\tilde{P}N$
- Receivers undo $\tilde{P}N$, reducing to per-satellite linear spreading codes $\tilde{M}L$

Key Security Issue

Reuse of Cryptographic Sequence

NB: Same cryptographic sequence $\tilde{P}N$ reused across all data sequences

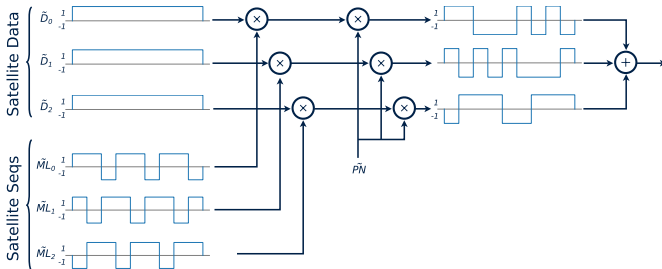

Key Security Issue

Reuse of Cryptographic Sequence

NB: Same cryptographic sequence $\tilde{P}N$ reused across all data sequences

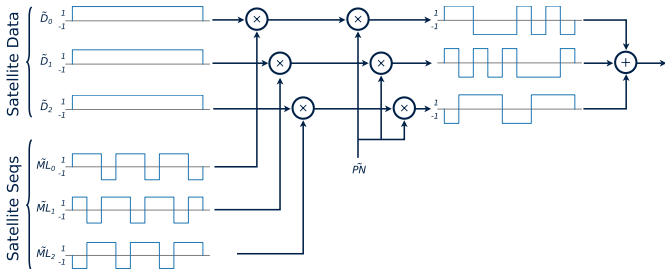

- Intuition: insufficient entropy entering the system to protect the data

Key Security Issue

Reuse of Cryptographic Sequence

NB: Same cryptographic sequence $\tilde{P}N$ reused across all data sequences

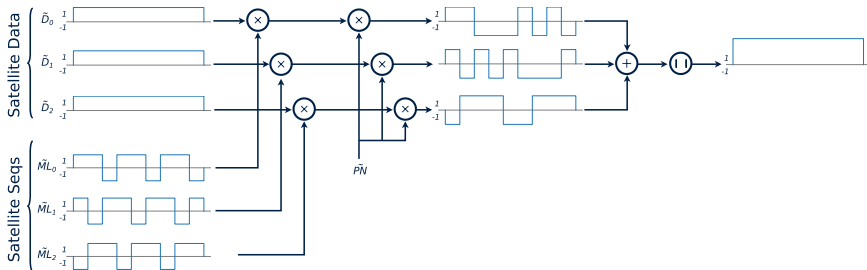

- Intuition: insufficient entropy entering the system to protect the data
- $\tilde{P}N$ has effect of randomising *sign* of aggregate chip, but not *magnitude*

Key Security Issue

Reuse of Cryptographic Sequence

NB: Same cryptographic sequence $\tilde{P}N$ reused across all data sequences

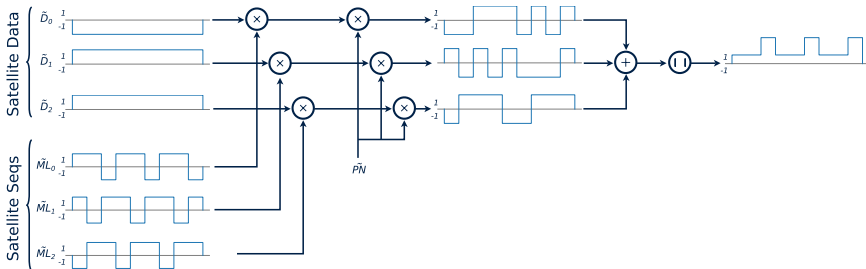

- Intuition: insufficient entropy entering the system to protect the data
- $\tilde{P}N$ has effect of randomising *sign* of aggregate chip, but not *magnitude*

Unobservability broken by correlating for known, repeating aggregate sequences
Q: In general case, how can the original data sequence be determined given a noisy waveform?

Attack: Eavesdropping

Adversarial Decoding

Algorithm 1 Eavesdropping Decoder Optimization

EAVESDROP($\mathbf{b}, \mathbf{ML}, \mathbf{g}$) $\rightarrow (\mathbf{D}^*, \mathbf{PN}^*)$ **Constants**

b_1, \dots, b_N	Received aggregate chips
ML_1, \dots, ML_n	Satellite ML sequences
g_1, \dots, g_n	Satellite gains

Variables

D_1, D_2, \dots, D_n	Data chip values
PN_1, \dots, PN_N	Cryptographic pseudo-noise
$e_1^+, e_1^-, \dots, e_N^+, e_N^-$	Error terms to minimize

Key principle: Find data D_i and pseudo-noise PN_i that minimize distance between received and expected chips.

Objective:

$$\text{Minimize } Z = e_1^+ + e_1^- + \dots + e_N^+ + e_N^-$$

Key Constraints:

$$\begin{aligned} g_1 ML_1[1] D_1 PN_1 + \dots + g_n ML_n[1] D_n PN_n + e_1^+ - e_1^- &= b_1 \\ \dots \\ g_1 ML_1[N] D_1 PN_N + \dots + g_n ML_n[N] D_n PN_N + e_N^+ - e_N^- &= b_N \end{aligned}$$

Bounding Constraints:

$$\begin{aligned} -1 &\leq D_1, \dots, D_n, PN_1, \dots, PN_N \leq 1 \\ e_1^+, e_1^-, e_2^+, e_2^- &\geq 0 \end{aligned}$$

Attack: Eavesdropping

Adversarial Decoding

Algorithm 1 Eavesdropping Decoder Optimization

 $\text{EAVESDROP}(\mathbf{b}, \mathbf{ML}, \mathbf{g}) \rightarrow (\mathbf{D}^*, \mathbf{PN}^*)$ **Constants**

b_1, \dots, b_N	Received aggregate chips
ML_1, \dots, ML_N	Satellite ML sequences
g_1, \dots, g_n	Satellite gains

Variables

D_1, D_2, \dots, D_n	Data chip values
PN_1, \dots, PN_N	Cryptographic pseudo-noise
$e_1^+, e_1^-, \dots, e_N^+, e_N^-$	Error terms to minimize

Key principle: Find data D_i and pseudo-noise PN_i that minimize distance between received and expected chips.

Objective:

Minimize $Z = e_1^+ + e_1^- + \dots + e_N^+ + e_N^-$

Key Constraints:

$$\begin{aligned}
 &g_1 ML_1[1] D_1 PN_1 + \dots + g_n ML_n[1] D_n PN_n + e_1^+ - e_1^- = b_1 \\
 &\dots \\
 &g_1 ML_1[N] D_1 PN_N + \dots + g_n ML_n[N] D_n PN_N + e_N^+ - e_N^- = b_N
 \end{aligned}$$

Bounding Constraints:

$$\begin{aligned}
 &-1 \leq D_1, \dots, D_n, PN_1, \dots, PN_N \leq 1 \\
 &e_1^+, e_1^-, e_2^+, e_2^- \geq 0
 \end{aligned}$$

- Solve optimisation problem by *Maximum Likelihood* decoding

Attack: Eavesdropping

Adversarial Decoding

Algorithm 1 Eavesdropping Decoder Optimization

 $\text{EAVESDROP}(\mathbf{b}, \mathbf{ML}, \mathbf{g}) \rightarrow (\mathbf{D}^*, \mathbf{PN}^*)$ **Constants**

- “What was the most likely transmitted data sequence given the waveform?”
- Takes into account many repeating chip magnitudes
- Catastrophic outcome: almost always reduces to 2 bits of entropy

Attack: Eavesdropping

Adversarial Decoding

Algorithm 1 Eavesdropping Decoder OptimizationEAVESDROP($\mathbf{b}, \mathbf{ML}, \mathbf{g}$) $\rightarrow (\mathbf{D}^*, \mathbf{PN}^*)$ **Constants**

b_1, \dots, b_N Received aggregate chips
 ML_1, \dots, ML_n Satellite ML sequences
 g_1, \dots, g_n Satellite gains

Variables

D_1, D_2, \dots, D_n Data chip values
 PN_1, \dots, PN_N Cryptographic pseudo-noise
 $e_1^+, e_1^-, \dots, e_N^+, e_N^-$ Error terms to minimize

Key principle: Find data D_i and pseudo-noise PN_i that minimize distance between received and expected chips.

Objective:Minimize $Z = e_1^+ + e_1^- + \dots + e_N^+ + e_N^-$ **Key Constraints:**

$$\begin{aligned}
 g_1 ML_1[1] D_1 PN_1 + \dots + g_n ML_n[1] D_n PN_n + e_1^+ - e_1^- &= b_1 \\
 \dots & \\
 g_1 ML_1[N] D_1 PN_N + \dots + g_n ML_n[N] D_n PN_N + e_N^+ - e_N^- &= b_N
 \end{aligned}$$

Bounding Constraints:

$$\begin{aligned}
 -1 \leq D_1, \dots, D_n, PN_1, \dots, PN_N &\leq 1 \\
 e_1^+, e_1^-, e_2^+, e_2^- &\geq 0
 \end{aligned}$$

- Solve optimisation problem by *Maximum Likelihood* decoding
- “What was the most likely transmitted data sequence given the waveform?”
- Takes into account many repeating chip magnitudes
- Catastrophic outcome: almost always reduces to 2 bits of entropy
- **Any** satellite’s data sequence is sufficient to recover **all** other satellites’ data

To create new messages, the attacker must know $\tilde{P}N$.

Q: How can $\tilde{P}N$ be recovered?

Attack: Spoofing

$\tilde{P}N$ Spreading Sequence Recovery

To create new messages, the attacker must know $\tilde{P}N$.

Q: How can $\tilde{P}N$ be recovered?

Attack: Spoofing

$\tilde{P}N$ Spreading Sequence Recovery

To create new messages, the attacker must know $\tilde{P}N$.

Q: How can $\tilde{P}N$ be recovered?

Attack: Spoofing

$\tilde{P}N$ Spreading Sequence Recovery

To create new messages, the attacker must know $\tilde{P}N$.

Q: How can $\tilde{P}N$ be recovered?

This recovers a noisy estimate of the spreading sequence

$$\tilde{P}N = \tilde{P}N_{est} + noise$$

Evaluation

Spoofing

Spoofing depends primarily on the noise in the spreading sequence estimate.
“Lifting” it from the noise floor through e.g. high gain antennas not required.

Countermeasures

Countermeasures

- Non-hybrid spread spectrum
 - Suffers up to 30 dB performance loss under multiple access
 - Secure hybrid systems for future standardisation must be secure against the presented attacks

Countermeasures

- Non-hybrid spread spectrum
 - Suffers up to 30 dB performance loss under multiple access
 - Secure hybrid systems for future standardisation must be secure against the presented attacks
- Preventing synchronization data reuse
 - Initialisation parameters are transmitted in the clear, allowing the adversary to record, modify, and replay as discussed
 - Authenticity protection and freshness guarantees required in session establishment

Countermeasures

- Non-hybrid spread spectrum
 - Suffers up to 30 dB performance loss under multiple access
 - Secure hybrid systems for future standardisation must be secure against the presented attacks
- Preventing synchronization data reuse
 - Initialisation parameters are transmitted in the clear, allowing the adversary to record, modify, and replay as discussed
 - Authenticity protection and freshness guarantees required in session establishment
- Cryptographic scrambling
 - Prevents recovery of the data sequences
 - Does not provide unobservability
 - Does not protect against bit-flipping spoofing attacks
